Lafii demo: voice-over script

15 lines, about two and a half minutes of speaking (the finished video runs about three). One audio file per line.

Save each line as its own file in **`demo/voiceover/`**, named by number: **`line01.m4a`** to **`line15.m4a`**. Any common audio format works (wav, mp3, m4a, aac, ogg, flac).

Record every line in the same room, at the same distance from the mic. Leave about half a second of silence before and after each line. Speak at your normal pace: the video holds or speeds up each screen to fit your clip. If you stumble, re-record just that line and overwrite its file.

Say CHPS as “chips”, and DHIMS2 as “D-H-I-M-S two”.

01 Setup: name, zone and facility filled in ~13s

This is Lafii, an app for Community Health Officers in Northern Ghana. Setting up takes one screen: her name, her CHPS zone and her facility. No account, no login, and no internet, ever.

02 Home: referrals to chase, women due this week ~7s

Amina's day opens on two lists: the referrals she is still waiting to hear back on, and the women due for a visit this week.

03 Find a woman: “Fati Alhas” finds two records ~12s

Fati Alhassan has come in without her card, so Amina searches by name. Spellings vary, so the search is forgiving. Each record shows community, age and last visit. There is no match score.

04 “These may be the same woman”: two cards side by side ~10s

Two records may be the same woman. The app shows them side by side, with equal weight, and never merges them on its own. Amina asks Fati, and chooses.

05 Antenatal visit 4, with the Speak instead button ~7s

This is Fati's fourth antenatal visit. Everything can be entered by tap, or Amina can speak the summary instead.

06 Blood pressure typed: 140 / 95 ~5s

Blood pressure: one forty over ninety five, typed on the phone's number pad.

07 Danger signs: Fits No, Bleeding No, Headache Yes ~12s

Every danger sign has three answers: yes, no, or not asked. A question nobody asked is never saved as a no. Fits: no. Bleeding: no. Severe headache: yes.

08 Consent in Dagbani, then the recording counter ~11s

To speak instead, the app first asks Fati's consent, in Dagbani. Speech is turned into text on the phone itself, and the audio is deleted as soon as the values are checked.

09 Back to the visit screen ~5s

Today Amina stays with tapping. Either way, the values arrive at the same check.

10 “Check what you recorded”: a value unconfirmed, then confirmed ~13s

Every value is confirmed one at a time. There is no confirm-all button. A value that has not been confirmed is left out of the assessment, and anything not recorded says Missing. Nothing is guessed.

11 Urgent: Signs of pre-eclampsia ~14s

The assessment comes from a fixed protocol rule, not from AI. High blood pressure with a severe headache: signs of pre-eclampsia, refer today. It shows exactly which values triggered it, and Amina can disagree and record why.

12 Referral code, signed QR, “Tell Fati” ~11s

Amina issues the referral. She writes this short code on Fati's paper card. The hospital scans the signed QR code with no network, and the app tells Amina what to say to Fati.

13 Home, then “Not yet arrived” ~10s

Back home, Fati joins the list of women who have not yet arrived, most serious first. When the hospital's acknowledgement is scanned, she comes off the list.

14 October report: register line and DHIMS2 figures ~8s

And the visit pays Amina back. Her register line and her monthly DHIMS2 figures are filled in for her, ready to export.

15 Home ~10s

One visit, entered once: a clinical record, a register line, a monthly report, and a referral that comes back. All on the phone. All offline.
